

Remarks

Favorable reconsideration of this application, in view of the above amendments and in light of the following remarks and discussion, is respectfully requested.

Claims 2 and 3 are currently pending in the application; Claims 2 and 3 having been amended, and Claim 1 and non-elected Claims 4-9 having been canceled without prejudice or disclaimer, by way of the present response.

In the outstanding Office Action, the drawings were objected to; the disclosure was objected to; Claims 1-3 were rejected under 35 U.S.C. § 112, second paragraph; Claim 1 was rejected under 35 U.S.C. § 102(b) as being anticipated by Publication No. SU 1605002 (the '002 Publication); Claim 2 was rejected under 35 U.S.C. § 102(b) as being anticipated by Japanese Publication No. 10-196303 to Eiichiro,¹ and Claim 1 was rejected under 35 U.S.C. § 103(a) as being unpatentable over U.S. Patent No. 5,221,181 to Ferleger et al. (Ferleger) in view of the '002 Publication.

Applicants express thanks for the Examiner's indication that independent Claim 3 recites allowable subject matter, and that therefore the claim would be allowable if amended to overcome the rejection under 35 U.S.C. § 112, second paragraph. For the reasons discussed in detail below, Applicants respectfully assert that the rejection has been overcome. Applicants respectfully assert that the claim has been further amended in a non-narrowing manner to remedy potential informalities and to place the claim in better condition for allowance. Thus, in accordance with the Examiner's indication of allowable subject matter, Applicants respectfully request the allowance of independent Claim 3.

In the Office Action, the drawings were objected to because Figures 14A, 16, 17, and 19A were required to be designated by a legend such as "Prior Art." In response, as shown in

¹ Enclosed is a computer English language translation, from the Japanese Patent Office website, of the Japanese Publication.

the attached replacement sheets, Applicants have so-designated these figures. Thus, Applicants respectfully request that this objection to the drawing be withdrawn.

In the Office Action, the drawings were objected to because in Figure 17, a lead line for reference numeral 25 was required. In response, as shown in the attached replacement sheets, Applicants have added the required lead line. Thus, Applicants respectfully request that this objection to the drawings be withdrawn.

In the Office Action, the disclosure was objected to because the specification stated “chip.” In response, as shown in the attached substitute specification, Applicants have amended the specification to state “tip” in place of the previous statements of “chip.” In accordance with 37 C.F.R. § 1.125(b), Applicants respectfully submit herewith a marked-up specification. Applicants respectfully assert that the substitute specification includes no new matter. Thus, Applicants respectfully request that the objection to the disclosure be withdrawn.

In the Office Action, Claims 1-3 were rejected under 35 U.S.C. § 112, second paragraph, because the claims recited “chip” or “chips.” In response, Applicants have amended the claims in a non-narrowing manner to recite “tip” and “tips” in place of the previous recitations of “chip” and chips,” respectively, and have canceled Claim 1. Thus, Applicants respectfully request that the objection to Claims 2 and 3 be withdrawn, and in accordance with the Examiner’s indication of allowable subject matter, that independent Claim 3 be allowed.

In the Office Action, Claim 1 was rejected under 35 U.S.C. § 102(b) as being anticipated by the ‘002 Publication. Claim 2 was rejected under 35 U.S.C. § 102(b) as being anticipated by Eiichiro. Claim 1 was rejected under 35 U.S.C. § 103(a) as being unpatentable over Ferleger in view of the ‘002 Publication. Applicants respectfully request that the

rejections of Claim 1 be withdrawn in view of the cancellation of the claim, and that the rejection of Claim 2 be withdrawn for the following reasons.

The present invention is directed to a blade structure in a gas turbine. Independent Claim 2 recites stationary blades arrayed in a circle on a casing, and moving blades arrayed in a circle on a rotor. A clearance is provided between tips of the moving blades and the casing. An entrance metal angle at a tip portion of the stationary blade that is the stationary blade at a rear stage of the moving blade having the tip clearance is smaller than an entrance metal angle at other portions than the tip portion of the stationary blade.

Regarding the rejection of independent Claim 2, Eiichiro is directed to a high performance blade. The Office Action asserts that Figures 1 and 2 of Eiichiro show “an entrance metal angle . . . at the tip portion of the stationary blade 1 . . . being smaller than an entrance metal angle at other positions . . . than the tip portion of the stationary blade, due to the blade inlet part 2 being protruded toward the belly side 4 of the blade 1 and formed in a curve shape forming a bow shape in a radial direction.”² Applicants respectfully traverse this assertion for the following reasons.

Specifically, Applicants respectfully assert that the Office Action has not established that Eiichiro teaches the claimed features of an entrance metal angle at a tip portion of a stationary blade smaller than an entrance metal angle at other portions than the tip portion of the stationary blade, as recited in independent Claim 2. Applicants respectfully assert that it is mere conjecture that Eiichiro shows such a relationship between entrance metal angles, as Eiichiro does not appear to state such a relationship, and does not show relevant portions of the blade with enough detail to support such a determination.

Applicants respectfully assert that Figure 1 of Eiichiro shows, in an aerofoil inlet port section 2 of an aerofoil 1, from a tip side to a base side, an amount of protrusion by a side of

² Page 6, lines 6-11 of text, of the Office Action.

an antinode 4 is enlarged gradually. The aerofoil 1, which is curved in an arc shape, is made to project most to the antinode 4 side in a center section in the height of the aerofoil 1.³

Applicants further respectfully assert that Figure 2 of Eiichiro shows the aerofoil 1 of Figure 1.⁴ Thus, Applicants respectfully assert that Eiichiro does not appear to show or state any relationship among entrance metal angles of portions of the aerofoil 1. Therefore, Applicants respectfully assert that the Office Action has failed to establish that Eiichiro teaches the claimed features recited in independent Claim 2.

Specifically, independent Claim 2 recites “an entrance metal angle at a tip portion of the stationary blade . . . is smaller than an entrance metal angle at other portions than the tip portion of the stationary blade.” Thus, Applicants respectfully request that the rejection of independent Claim 2 under 35 U.S.C. § 102(b) be withdrawn.

Consequently, in view of the present amendment, no further issues are believed to be outstanding in the present application, and the present application is believed to be in condition for formal Allowance. A Notice of Allowance for Claims 2 and 3 is earnestly solicited.

BLADE STRUCTURE IN A GAS TURBINE

FIELD OF THE INVENTION

This invention relates to a blade structure in a gas turbine. More particularly, this invention relates to a blade structure of a gas turbine with improved turbine efficiency by restricting pressure loss to a minimum level.

BACKGROUND OF THE INVENTION

A gas turbine will be explained with reference to Fig. 16. In general, a gas turbine is equipped with a plurality of stages of stationary blades 2 and 3 arrayed in a circle on a casing (a blade circle or a vehicle chamber) 1, and a plurality of moving blades 5 arrayed in a circle on a rotor (a hub of a base) 4. Fig. 16 shows the moving blade 5 at a certain stage, the stationary blade 2 at the same stage (the inlet side of combustion gas 6) as this moving blade 5, and the stationary blade 3 at the next stage (the outlet side of the combustion gas 6) of this moving blade 5.

When pressure loss is large in the gas turbine, turbine efficiency is lowered. Therefore, it is important to improve the turbine efficiency by minimizing the pressure loss.

However, as shown in Fig. 16, there is a case where the moving blade 5 at a certain stage is what is called a

free-standing moving blade that has a clearance 8 between
a chiptip 7 of this moving blade 5 and the casing 1. In
the case of this free-standing moving blade 5, there is the
following problem.

5 Namely, as shown in Fig. 17, a main flow (shown by
a solid-line arrow mark in Fig. 17) of combustion gas 6 flows
to the next-stage stationary blade 3 side by passing through
between the moving blade 5 and the moving blade 5. In the
mean time, in the clearance 8 between the chiptip 7 of the
10 moving blade 5 and the casing 1, there is generated a leakage
flow 9 (shown by a broken-line arrow mark in Fig. 17) that
is separate from the main flow of the combustion gas 6.

A mechanism of generating the leakage flow 9 is that
as the pressure at a belly surface 10 side of the moving
15 blade 5 is higher than the pressure at a rear surface 11
side of the moving blade 5, the leakage flow 9 is generated
from the belly surface 10 side to the rear surface 11 side
based on a difference between these pressures.

As shown in Fig. 17, the leakage flow 9 flows at an
20 incidence angle i_c to the rear surface 13 side at a front
edge 12 of the chiptip of the stationary blade 3 at the next
stage. This leakage flow 9 becomes a flow opposite to the
main flow of the combustion gas 6 that flows to the belly
surface 14 side of the stationary blade 3.

25 Therefore, a vortex flow 15 (shown by a solid-line

spiral arrow mark in Fig. 17) is generated at the belly surface 14 side of the front edge 12 of the ehiptip of the stationary blade 3. When this vortex flow 15 is generated, pressure loss occurs. The main flow of the combustion gas 6 may deviate from the belly surface 14 side of the stationary blade 3. In Fig. 17, a reference symbol β_c denotes an entrance metal angle at the ehiptip portion of the stationary blade 3. Similarly, a reference symbol θ_c denotes a front-edge including angle at the ehiptip portion of the stationary blade 3. Similarly, a reference number 22 denotes a camber line for connecting between the front edge 12 of the ehiptip portion of the stationary blade 3 and a rear edge 23 of the ehiptip portion.

The incidence angle i_c of the leakage flow 9 and the pressure loss have a relative relationship as shown by a solid-line curve in Fig. 18. The solid-line curve in Fig. 18 shows a case of the front-edge including angle θ_c at the ehiptip portion of the stationary blade 3 shown in Fig. 17.

In this case, the front-edge including angle θ_c at the ehiptip portion of the stationary blade 3 has been set such that the pressure loss becomes minimum (refer to a point P1 in Fig. 18). However, as described above, the leakage flow 9 is generated, and the pressure loss also becomes large when the incidence angle i_c of this leakage flow 9 is large (refer to a point P2 in Fig. 18). When this pressure loss

is large, the turbine efficiency is lowered by that amount.

Further, as shown in Fig. 16, seal-air 16 (shown by a two-dot chained line arrow mark in Fig. 16) flows from the rotor 4 side at the upstream of the moving blade 5 at a certain stage. When this seal-air 16 is flowing, there is the following problem.

Namely, the seal-air 16 simply flows out straight in a direction of the height (a radial direction of the turbine) of the moving blade 5 without being squeezed by a nozzle or the like. On the other hand, the moving blade 5 is rotating in a direction of an outline arrow mark together with the rotor 4. Therefore, from the relative relationship between the flow-out of the seal-air 16 and the rotation of the moving blade 5, the seal-air 16 flows at the incidence angle is to the rear-surface side 11 at the front edge 17 of the hub portion of the moving blade 5, as shown in Fig. 17.

As explained above, when the incidence angle is of the seal-air 16 becomes large at the front edge 17 of the hub portion of the moving blade 5 as well, the pressure loss becomes large and the turbine efficiency is lowered by that amount as shown in Fig. 17 and Fig. 18, in a similar manner to that at the front edge 12 of the ~~chiptip~~chiptip portion of the stationary blade 3.

This problem of the hub portion of the moving blade 5 also applies to a shrouded moving blade in addition to

the above-described free-standing moving blade. In Fig. 17, a reference symbol β_s denotes an entrance metal angle at the hub portion of the moving blade 5. Similarly, a reference symbol θ_s denotes a front-edge including angle at the hub portion of the moving blade 5. Similarly, a reference number 24 denotes a camber line for connecting between the front edge 17 of the hub portion of the moving blade 5 and a rear edge 25 of the hub portion.

Further, when the moving blade 5 at a certain stage is a free-standing moving blade, there is the following problem.

Namely, as shown in Fig. 17, the leakage flow 9 is generated from the belly surface 10 side of the moving blade 5 to the rear surface 11 side, at the clearance 8 between the chiptip 7 of the free-standing moving blade 5 and the casing 1.

Then, as shown in Fig. 19B, a design Mach number distribution shown by a solid-line curve becomes an actual Mach number distribution as shown by a broken-line curve. As a result, on the rear surface 11 of the chiptip portion 18 of the moving blade 5, deceleration from an intermediate portion to a rear edge 19 is larger in actual Mach distribution G2 than in design Mach distribution G1.

When the deceleration is large, as shown in Fig. 19A, a boundary layer (a portion provided with shaded lines) 20

at a portion from the intermediate portion to the rear edge
19 swells on the rear surface 11 of the ~~chiptip~~tip portion 18
of the moving blade 5. As a result, the pressure loss becomes
large, and the turbine efficiency is lowered by that amount.
5 A reference number 21 in Fig. 19 denotes a front edge of
the ~~chiptip~~tip portion 18 of the moving blade 5.

SUMMARY OF THE INVENTION

It is an object of this invention to provide a blade
10 structure in a gas turbine capable of improving the turbine
efficiency by minimizing the pressure loss.

In the blade structure in a gas turbine according to
one aspect of this invention, a front-edge including angle
at a ~~chiptip~~tip portion of the stationary blade that is the
15 stationary blade at the rear stage of the moving blade having
the ~~chiptip~~tip clearance is larger than a front-edge including
angle at other portions than the ~~chiptip~~tip portion of the
stationary blade.

According to the above-mentioned aspect, a curve of
20 a relative relationship between the incidence angle and the
pressure loss becomes mild by making the front-edge including
angle large. It is possible to reduce the pressure loss
by that amount, and therefore, it becomes possible to improve
the turbine efficiency.

25 In the blade structure in a gas turbine according to

another aspect of this invention, an entrance metal angle
at a ehiptip portion of the stationary blade that is the
stationary blade at the rear stage of the moving blade having
the ehiptip clearance is made smaller than an entrance metal
5 angle at other portions than the ehiptip portion of the
stationary blade.

According to the above-mentioned aspect, it is
possible to make the incidence angle small by making the
entrance metal angle small. It is possible to reduce the
10 pressure loss by that amount, and therefore, it becomes
possible to improve the turbine efficiency.

In the blade structure in a gas turbine according to
still another aspect of this invention, a front-edge
including angle at a ehiptip portion of the stationary blade
15 that is the stationary blade at the rear stage of the moving
blade having the ehiptip clearance is made larger than a
front-edge including angle at other portions than the ehiptip
portion of the stationary blade, and also an entrance metal
angle at a ehiptip portion of the stationary blade is made
20 smaller than an entrance metal angle at other portions than
the ehiptip portion of the stationary blade.

According to the above-mentioned aspect, a curve of
a relative relationship between the incidence angle and the
pressure loss becomes mild by making the front-edge including
25 angle large. It is possible to reduce the pressure loss

by that amount, and therefore, it becomes possible to improve the turbine efficiency. Moreover, it is possible to make the incidence angle small by making the entrance metal angle small. Also, it is possible to reduce the pressure loss
5 by that amount, and therefore, it becomes possible to improve the turbine efficiency. Moreover, it is possible to make the pressure loss much smaller based on a synergy effect of the work that a curve of a relative relationship between the incidence angle and the pressure loss becomes mild and
10 the work that the incidence angle can be made small.

In the blade structure in a gas turbine according to still another aspect of this invention, a front-edge including angle at a hub portion of the stationary blade is made larger than a front-edge including angle at other
15 portions than the hub portion of the moving blade.

According to the above-mentioned aspect, a curve of a relative relationship between the incidence angle and the pressure loss becomes mild by making the front-edge including angle large. It is possible to reduce the pressure loss
20 by that amount, and therefore, it becomes possible to improve the turbine efficiency.

In the blade structure in a gas turbine according to still another aspect of this invention, an entrance metal angle at a hub portion of the stationary blade is made smaller
25 than an entrance metal angle at other portions than the hub

portion of the moving blade.

According to the above-mentioned aspect, it is possible to make the incidence angle small by making the entrance metal angle small. It is possible to reduce the pressure loss by that amount, and therefore, it becomes possible to improve the turbine efficiency.

In the blade structure in a gas turbine according to still another aspect of this invention, a front-edge including angle at a hub portion of the stationary blade is made larger than a front-edge including angle at other portions than the hub portion of the moving blade, and also an entrance metal angle at a hub portion of the stationary blade is made smaller than an entrance metal angle at other portions than the hub portion of the moving blade.

According to the above-mentioned aspect, a curve of a relative relationship between the incidence angle and the pressure loss becomes mild by making the front-edge including angle large. It is possible to reduce the pressure loss by that amount, and therefore, it becomes possible to improve the turbine efficiency. Moreover, it is possible to make the incidence angle small by making the entrance metal angle small. It is possible to reduce the pressure loss by that amount, and therefore, it becomes possible to improve the turbine efficiency. Furthermore, it is possible to make the pressure loss much smaller based on a synergy effect

of the work that a curve of a relative relationship between the incidence angle and the pressure loss becomes mild and the work that the incidence angle can be made small.

In the blade structure in a gas turbine according to
5 still another aspect of this invention, a chord length at
a ehiptip portion of the moving blade having the ehiptip
clearance is made larger than a minimum chord length at other
portions than the ehiptip portion of the moving blade.

According to the above-mentioned aspect, it is
10 possible to make small the deceleration from the intermediate
portion to the rear edge on the rear surface of the ehiptip
portion of the moving blade by making the chord length of
the moving blade large. Then, it is possible to minimize
the swelling of the boundary layer. As a result, it is
15 possible to make the pressure loss small, and it becomes
possible to improve the turbine efficiency by that amount.

Other objects and features of this invention will
become apparent from the following description with
reference to the accompanying drawings.

15

DETAILED DESCRIPTION

Embodiments of a blade structure in a gas turbine relating to this invention will be explained below with reference to the accompanying drawings. It should be noted
20 that the blade structure in the gas turbine is not limited to these embodiments.

Fig. 1 is an explanatory diagram showing a first embodiment of a blade structure in a gas turbine relating to this invention. In the drawing, reference numbers that
25 are the same as those in Fig. 16 to Fig. 19 show the identical

portions.

A blade structure in a first embodiment relates to a stationary blade 3 at the rear stage of a moving blade having a ehiptip clearance. A front-edge including angle θ_{c1} at a front edge of a ehiptip portion (a cross section of a ehiptip) of the stationary blade 3 is made larger than a front-edge including angle of portions (a cross section of a hub portion to a mean portion) other than the ehiptip portion of this stationary blade 3. For example, this is made larger than about 5° .

According to the blade structure of this first embodiment, the front-edge including angle θ_{c1} is taken large at the ehiptip portion of the stationary blade 3 at the rear stage of the moving blade having the ehiptip clearance. With this arrangement, a curve of a relative relationship between the incidence angle and the pressure loss becomes mild as shown by a broken-line curve in Fig. 18. As a result, it is possible to make the pressure loss small as shown by a point P3 in Fig. 18. Therefore, it becomes possible to improve the turbine efficiency.

Fig. 2 is an explanatory diagram showing a second embodiment of a blade structure in a gas turbine relating to this invention. In the drawing, reference numbers that are the same as those in Fig. 1 and Fig. 16 to Fig. 19 show the identical portions.

A blade structure in a second embodiment relates to a stationary blade 3 at the rear stage of a moving blade having a ehiptip clearance. An entrance metal angle β_{c1} of a ehiptip portion (a cross section of a ehiptip) of this stationary blade 3 is made smaller than an entrance metal angle of portions (a cross section of a hub portion to a mean portion) other than the ehiptip portion of this stationary blade 3. In other words, the entrance metal angle β_{c1} of the cross section of the ehiptip portion of the stationary blade 3 is directed toward a rear surface 13 side by about 10° , for example, as compared with the entrance metal angle of the cross section of the hub portion to the mean portion.

According to the blade structure of this second embodiment, the entrance metal angle β_{c1} is taken small at the ehiptip portion of the stationary blade 3 at the rear stage of the moving blade having the ehiptip clearance. With this arrangement, it is possible to make an incidence angle $ic1$ small as shown by a point P4 in Fig. 18. As a result, it is possible to make the pressure loss small. Therefore, it becomes possible to improve the turbine efficiency.

Fig. 3 and Fig. 4 are explanatory diagrams showing a third embodiment of a blade structure in a gas turbine relating to this invention. In the drawings, reference numbers that are the same as those in Fig. 1, Fig. 2 and

Fig. 16 to Fig. 19 show the identical portions.

A blade structure in a third embodiment relates to a stationary blade 3 at the rear stage of a moving blade having a ehiptip clearance. A front-edge including angle θ_{c1} at a front edge of a ehiptip portion (a cross section of a ehiptip) of the stationary blade 3 is made larger than a front-edge including angle of portions (a cross section of a hub portion to a mean portion) other than the ehiptip portion of this stationary blade 3. For example, this is made larger than about 5° .

Further, an entrance metal angle β_{c1} of a ehiptip portion (a cross section of a ehiptip) of this stationary blade 3 is made smaller than an entrance metal angle of portions (a cross section of a hub portion to a mean portion) other than the ehiptip portion of this stationary blade 3. In other words, the entrance metal angle β_{c1} of the cross section of the ehiptip portion of the stationary blade 3 is directed toward a rear surface 13 side by about 10° , for example, as compared with the entrance metal angle of the cross section of the hub portion to the mean portion.

According to the blade structure of this third embodiment, the front-edge including angle θ_{c1} is taken large at the ehiptip portion of the stationary blade 3 at the rear stage of the moving blade having the ehiptip clearance. With this arrangement, a curve of a relative relationship between

the incidence angle and the pressure loss becomes mild as shown by the broken-line curve in Fig. 18. As a result, it is possible to make the pressure loss small as shown by the point P3 in Fig. 18. Therefore, it becomes possible
5 to improve the turbine efficiency.

Further, according to the blade structure of this third embodiment, the entrance metal angle β_{c1} is taken small at the chiptip portion of the stationary blade 3 at the rear stage of the moving blade having the chiptip clearance. With
10 this arrangement, it is possible to make an incidence angle $ic1$ small as shown by the point P4 in Fig. 18. As a result, it is possible to make the pressure loss small. Therefore, it becomes possible to improve the turbine efficiency.

Particularly, according to the blade structure of this
15 third embodiment, it is possible to make the pressure loss much smaller, based on a synergy effect of the work that a curve of a relative relationship between the incidence angle and the pressure loss becomes mild as shown by the broken-line curve in Fig. 18 and the work that the incidence
20 angle $ic1$ can be made small as shown by a point P5 in Fig. 18. As a result, it becomes possible to improve the turbine efficiency.

Fig. 5 is an explanatory diagram showing a first embodiment of a blade structure in a gas turbine relating
25 to this invention. In the drawing, reference numbers that

are the same as those in Fig. 1 to Fig. 4 and Fig. 16 to Fig. 19 show the identical portions.

A blade structure in a fourth embodiment relates to a moving blade 5 like a free-standing moving blade and a shrouded moving blade. A front-edge including angle θ_{s1} at a hub portion (a cross section of a hub portion) of this moving blade 5 is made larger than a front-edge including angle of portions (a cross section of a ~~chiptip~~ chiptip portion to a mean portion) other than the hub portion of this moving blade 5. For example, this is made larger than about 5° .

According to the blade structure of this fourth embodiment, the front-edge including angle θ_{s1} is taken large at the hub portion of this moving blade 5. With this arrangement, a curve of a relative relationship between the incidence angle and the pressure loss becomes mild as shown by the broken-line curve in Fig. 18. As a result, it is possible to make the pressure loss small as shown by the point P3 in Fig. 18. Therefore, it becomes possible to improve the turbine efficiency.

Fig. 6 is an explanatory diagram showing a fifth embodiment of a blade structure in a gas turbine relating to this invention. In the drawing, reference numbers that are the same as those in Fig. 1 to Fig. 5 and Fig. 16 to Fig. 19 show the identical portions.

A blade structure in a fifth embodiment relates to

a moving blade 5 like a free-standing moving blade and a shrouded moving blade. An entrance metal angle β_{s1} of a hub portion (a cross section of a hub portion) of this moving blade 5 is made smaller than an entrance metal angle of portions (a cross section of a ~~chiptip~~ chiptip portion to a mean portion) other than the hub portion of this moving blade 5. In other words, the entrance metal angle β_{s1} of the cross section of the hub portion of the moving blade 5 is directed toward a rear surface 11 side by about 10° , for example, as compared with the entrance metal angle of the cross section of the ~~chiptip~~ chiptip portion to the mean portion.

According to the blade structure of this fifth embodiment, the entrance metal angle β_{s1} is taken small at the hub portion of the moving blade 5. With this arrangement, it is possible to make an incidence angle i_{s1} small as shown by the point P4 in Fig. 18. As a result, it is possible to make the pressure loss small. Therefore, it becomes possible to improve the turbine efficiency.

Fig. 7 and Fig. 8 are explanatory diagrams showing a sixth embodiment of a blade structure in a gas turbine relating to this invention. In the drawings, reference numbers that are the same as those in Fig. 1 to Fig. 6 and Fig. 16 to Fig. 19 show the identical portions.

A blade structure in a sixth embodiment relates to a moving blade 5 like a free-standing moving blade and a

shrouded moving blade. A front-edge including angle θ_{s1} at a hub portion (a cross section of a hub portion) of this moving blade 5 is made larger than a front-edge including angle of portions (a cross section of a ~~chiptip~~ portion to a mean portion) other than the hub portion of this moving blade 5. For example, this is made larger than about 5° .

Further, an entrance metal angle β_{s1} of a hub portion (a cross section of a hub portion) of this moving blade 5 is made smaller than an entrance metal angle of portions (a cross section of a ~~chiptip~~ portion to a mean portion) other than the hub portion of this moving blade 5. In other words, the entrance metal angle β_{s1} of the cross section of the hub portion of the moving blade 5 is directed toward a rear surface 11 side by about 10° , for example, as compared with the entrance metal angle of the cross section of the ~~chiptip~~ portion to the mean portion.

According to the blade structure of this sixth embodiment, the front-edge including angle θ_{s1} is taken large at the hub portion of this moving blade 5. With this arrangement, a curve of a relative relationship between the incidence angle and the pressure loss becomes mild as shown by the broken-line curve in Fig. 18. As a result, it is possible to make the pressure loss small as shown by the point P3 in Fig. 18. Therefore, it becomes possible to improve the turbine efficiency.

Further, according to the blade structure of this sixth embodiment, the entrance metal angle β_{s1} is taken small at the hub portion of the moving blade 5. With this arrangement, it is possible to make an incidence angle i_{s1} small as shown by the point P4 in Fig. 18. As a result, it is possible to make the pressure loss small. Therefore, it becomes possible to improve the turbine efficiency.

Particularly, according to the blade structure of this sixth embodiment, it is possible to make the pressure loss much smaller, based on a synergy effect of the work that a curve of a relative relationship between the incidence angle and the pressure loss becomes mild as shown by the broken-line curve in Fig. 18 and the work that the incidence angle i_{s1} can be made small as shown by the point P5 in Fig. 18. As a result, it becomes possible to improve the turbine efficiency.

Fig. 9 and Fig. 12 are explanatory diagrams showing a seventh embodiment of a blade structure in a gas turbine relating to this invention. In the drawings, reference numbers that are the same as those in Fig. 1 to Fig. 8 and Fig. 16 to Fig. 19 show the identical portions.

A blade structure in a seventh embodiment relates to a moving blade 5 like a free-standing moving blade and a shrouded moving blade. A chord length 26 at a chiptip portion 18 (a cross section of the chiptip portion 18) of this moving

blade 5 is made larger than a minimum chord length at other portions (a cross section of a hub portion to a mean section) than the ~~ehiptip~~ portion of the moving blade 5. In other words, the chord length 26 of the cross section of the ~~ehiptip~~ portion 18 is made equal to or larger than the chord length of the mean cross section (a ratio of pitch to chord is set larger than a conventional ratio).

Fig. 9 is an explanatory diagram of a cross section showing a stacking shape of the moving blade 5. In Fig. 9 to Fig. 11, a stacking shape shown by a reference number 50 and a solid line show a ~~ehiptip~~. A stacking shape shown by a reference number 51 and a one-dot chained line show a ~~ehiptip~~ at a position of about 75% of the height from a hub. Further, a stacking shape shown by a reference number 52 and a two-dot chained line show a mean. Further, a stacking shape shown by a reference number 53 and a three-dot chained line show a ~~ehiptip~~ at a position of about 25% of the height from the hub. Last, a stacking shape shown by a reference number 54 and a broken line show the hub.

According to the blade structure of this sixth embodiment, it is possible to make small the deceleration from an intermediate portion to a rear edge 19 on a rear surface 11 of a ~~ehiptip~~ portion 18 of a moving blade 5, as shown by G4 in Fig. 12B, by making large a chord length 26 of the ~~ehiptip~~ portion 18 of the moving blade 5.

Namely, in Mach number distributions in Fig. 12B and Fig. 19B, an area of a portion encircled by a solid-line curve (an area of a portion provided with shaded lines, and a pressure difference) S is constant. In this case, when
5 | the chord length 26 of the ~~chip~~tip portion 18 of the moving blade 5 is made large, the area S of the Mach number distribution changes from a vertically-long shape shown in Fig. 19B to a laterally-long shape shown in Fig. 12B. As a result, the deceleration changes from $G2$ shown in Fig.
10 | 19B to small $G4$ shown in Fig. 12B. Consequently, it is possible to restrict the swelling of the boundary layer. Therefore, it is possible to make the pressure loss small, and it becomes possible to improve the turbine efficiency by that amount.

15 | Fig. 13 to Fig. 15 show modifications of a blade structure in a gas turbine relating to this invention. In these drawings, reference numbers that are the same as those in Fig. 1 to Fig. 12 and Fig. 16 to Fig. 19 show the identical portions.

20 | First, a modification shown in Fig. 13 is a modification of the seventh embodiment. ~~Chip~~Tip portions of stationary blades 2 and 3 are provided with escape sections 27 for
| avoiding an interference with a ~~chip~~tip portion 18 of a moving blade 5.

25 | According to this seventh embodiment, there is no room

for mutual interference between the ehiptip portion 18 of the moving blade 5 and the ehiptip portions of the stationary blades 2 and 3 adjacent to each other, even when the chord length 26 of the ehiptip portion 18 of the moving blade 5 is made large. A two-dot chained line in Fig. 13 shows a conventional blade structure.

Next, a modification shown in Fig. 14B is a modification of the seventh embodiment. As an escape section of the ehiptip portion of the stationary blade 3, the entrance metal angle β_{c1} of the ehiptip portion of the stationary blade 3 is made smaller than the entrance metal angle of portions (the hub portion to the mean portion) other than the ehiptip portion of the stationary blade 3. In other words, as shown in Fig. 2, Fig. 3 and Fig. 4, the entrance metal angle β_{c1} of the ehiptip portion of the stationary blade 3 is directed toward the rear surface 13 side of the stationary blade 3. It is also possible to have a similar structure for the stationary blade 2 at the same stage as that of the moving blade 5.

According to the modification shown in this Fig. 14B, as the entrance metal angle β_{c1} of the ehiptip portion of the stationary blade 3 is directed toward the rear surface 13 side of the stationary blade 3, it is possible to have a width $W1$ in an axial direction of the stationary blade 3 smaller than a width $W2$ of a conventional moving blade

shown in Fig. 14A. As a result, even when a width W3 in the axial direction of the moving blade 5 is made larger than a conventional width W4 by increasing the chord length 26 of the ~~chiptip~~ portion 18 of the moving blade 5, a width W5 from the moving blade 5 to the stationary blade 3 makes little change from a conventional width W6. Therefore, there is no room for mutual interference between the ~~chiptip~~ portion 18 of the moving blade 5 and the ~~chiptip~~ portion of the stationary blade 3 adjacent to each other, even when the chord length 26 of the ~~chiptip~~ portion 18 of the moving blade 5 is made large.

Further, according to the modification shown in this Fig. 14B, as the entrance metal angle β_{c1} of the ~~chiptip~~ portion of the stationary blade 3 is smaller than the entrance metal angle of the hub portion to the mean portion other than the ~~chiptip~~ portion of the stationary blade 3, it becomes possible to make the incidence angle i_{c1} small as shown by the point P4 in Fig. 18. As it is possible to make the pressure loss smaller by that amount, it becomes possible to improve the turbine efficiency.

Then, the blade structure relating to this invention can also be applied to a cooling moving blade 29 having a hollow portion 28 at the ~~chiptip~~ portion 18, as shown in Fig. 15A. Further, it is also possible to apply the blade structure relating to this invention to a moving blade 31

of which ehiptip portion 18 has a taper 30 along the taper of the casing 1, as shown in Fig. 15B.

As is clear from the above, according to the blade structure in a gas turbine relating to one aspect of this invention, a front-edge including angle is taken large, at
5 | a ehiptip portion of a stationary blade at a rear stage of a moving blade having a ehiptip clearance. Therefore, a curve of a relative relationship between the incidence angle and the pressure loss becomes mild. As it is possible to
10 | reduce the pressure loss by that amount, it becomes possible to improve the turbine efficiency.

According to the blade structure in a gas turbine relating to another aspect of this invention, it is possible to make an incidence angle small by making an entrance metal
15 | angle small, at a ehiptip portion of a stationary blade at a rear stage of a moving blade having a clearance. As it is possible to reduce the pressure loss by that amount, it becomes possible to improve the turbine efficiency.

According to the blade structure in a gas turbine relating to still another aspect of this invention, a
20 | front-edge including angle is taken large at a ehiptip portion of a stationary blade, at a rear stage of a moving blade having a ehiptip clearance. Therefore, a curve of a relative relationship between an incidence angle and a
25 | pressure loss becomes mild. As it is possible to reduce

the pressure loss by that amount, it becomes possible to improve the turbine efficiency.

According to the blade structure in a gas turbine relating to still another aspect of this invention, it is possible to make an incidence angle small by making an entrance metal angle small, at a ~~chiptip~~chiptip portion of a stationary blade at a rear stage of a moving blade having a clearance. As it is possible to reduce the pressure loss by that amount, it becomes possible to improve the turbine efficiency.

According to the blade structure in a gas turbine relating to still another aspect of this invention, it is possible to make the pressure loss much smaller based on a synergy effect of the work that a curve of a relative relationship between an incidence angle and a pressure loss becomes mild and the work that the incidence angle can be made small. As a result, it becomes possible to improve the turbine efficiency.

According to the blade structure in a gas turbine relating to still another aspect of this invention, a curve of a relative relationship between an incidence angle and a pressure loss becomes mild by making a front-edge including angle large at a hub portion of a moving blade. As it is possible to reduce the pressure loss by that amount, it becomes possible to improve the turbine efficiency.

According to the blade structure in a gas turbine relating to still another aspect of this invention, it is possible to make an incidence angle small by making an entrance metal angle small at a hub portion of a moving blade.

5 As it is possible to reduce the pressure loss by that amount, it becomes possible to improve the turbine efficiency.

According to the blade structure in a gas turbine relating to still another aspect of this invention, a curve of a relative relationship between an incidence angle and

10 a pressure loss becomes mild by making a front-edge including angle large at a hub portion of a moving blade. As it is possible to reduce the pressure loss by that amount, it becomes possible to improve the turbine efficiency.

According to the blade structure in a gas turbine

15 relating to still another aspect of this invention, it is possible to make an incidence angle small by making an entrance metal angle small at a hub portion of a moving blade. As it is possible to reduce the pressure loss by that amount, it becomes possible to improve the turbine efficiency.

20 According to the blade structure in a gas turbine relating to still another aspect of this invention, it is possible to make the pressure loss much smaller based on a synergy effect of the work that a curve of a relative relationship between an incidence angle and a pressure loss

25 becomes mild and the work that the incidence angle can be

made small. As a result, it becomes possible to improve the turbine efficiency.

According to the blade structure in a gas turbine relating to still another aspect of this invention, it is possible to make small the deceleration from an intermediate portion to a rear edge on a rear surface of a ehiptip portion of a moving blade by making a chord length of the moving blade large. Then, it is possible to minimize the swelling of the boundary layer. As a result, it is possible to make the pressure loss small, and it becomes possible to improve the turbine efficiency by that amount.

Furthermore, a ehiptip portion of a stationary blade is provided with an escape section for avoiding an interference with a ehiptip portion of a moving blade. As a result, there is no room for mutual interference between a ehiptip portion of the moving blade and ehiptip portions of stationary blades adjacent to each other, even when a chord length of the ehiptip portion of the moving blade is made large.

Moreover, as an entrance metal angle at a ehiptip portion of a stationary blade is directed toward the rear surface side of the stationary blade, there is no room for mutual interference between a ehiptip portion of a moving blade and ehiptip portions of stationary blades adjacent to each other, even when the chord length of the ehiptip

portion of the moving blade is made large.

Furthermore, as an entrance metal angle at a ~~chiptip~~tip portion of a stationary blade is smaller than an entrance metal angle at other portions than the ~~chiptip~~tip portion of the stationary blade, it is possible to make an incidence angle small. As it is possible to reduce the pressure loss by that amount, it becomes possible to improve the turbine efficiency.

Although the invention has been described with respect to a specific embodiment for a complete and clear disclosure, the appended claims are not to be thus limited but are to be construed as embodying all modifications and alternative constructions that may occur to one skilled in the art which fairly fall within the basic teaching herein set forth.

ABSTRACT OF THE DISCLOSURE

In the blade structure in a gas turbine, front-edge including angles are made large. As a result, a curve of a relative relationship between incidence angles ic_1 and is_1 and pressure loss becomes mild. Entrance metal angles are made small. As a result, it becomes possible to make the incidence angles small. Chord length of a ehiptip portion of a moving blade is made large. As a result, it becomes possible to make small the deceleration on a rear surface of the ehiptip portion of the moving blade. Accordingly, it becomes possible to make the pressure loss small, and therefore, it becomes possible to improve the turbine efficiency.
